Architecture

Detailed Description

Kubernetes `Deployments` serve as a blueprint for running your application in a cluster. Building on `ReplicaSets`, they ensure your application remains in the desired state by maintaining the defined number of instances.

ReplicaSets take care of the following:

- Ensuring the desired number of Pods are always running
- Replacing failed Pods automatically to maintain the specified replicas

On top of that, a Deployment adds features, such as:

- Automatically rolling out new versions of your application
- Rolling back to a previous version if something goes wrong
- Managing updates with strategies like rolling updates or recreating Pods

When a deployment in Kubernetes performs an upgrade (for example, if you change the image or other pod specifications), a rolling upgrade strategy is created by default. This manages the ReplicaSets to ensure minimal downtime and meet the constraints set by `maxUnavailable` and `maxSurge`. The Deployment maintains a current ReplicaSet (for the existing pods) and creates a new ReplicaSet for the updated pods. During the update, pods are gradually scaled down in the old ReplicaSet and scaled up in the new ReplicaSet.

revisionHistoryLimit The Number of old replicas to retain for rollback.

strategy Defines the deployment strategy, Default `RollingUpdate` or `Recreate`.

- `Recreate`: All existing Pods are destroyed before new ones are created
- `RollingUpdate`: Updates Pods in a rolling update fashion (`maxUnavailable`; `maxUnavailable`)

maxUnavailable The maximum number of pods that can be unavailable (not running or ready) during the update. Default: 25% Ensures a certain number of old pods remain running during the update to handle requests.

Example: If there are 4 replicas in a Deployment and `maxUnavailable` is set to 1:

- At most, 1 pod can be unavailable during the update.
- Kubernetes will ensure at least 3 pods (old or new) are running at any given time.

maxSurge The maximum number of extra pods that can be created beyond the desired replicas during the update. Default: 25% Determines how many new pods can be created during the update to replace old pods.

Example: If there are 4 replicas in a Deployment and `maxSurge=1`:

- Up to 5 pods (4 original + 1 new) can be running at once during the update.

Command Reference Guide

Remember to use dry-run and tee to check the configuration of each command first.

```
--dry-run=client -o yaml | tee nginx-deployment.yaml
```

Create a ReplicaSet using a YAML file (declarative method)

nginx-replicaset.yaml

```
apiVersion: apps/v1
kind: ReplicaSet
metadata:
  name: nginx-replicaset
spec:
  replicas: 3
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
        - name: nginx
          image: nginxdemos/hello
          ports:
            - containerPort: 80
```

Apply replicaset

```
kubectl apply -f nginx-replicaset.yaml
```

Get ReplicaSet information

```
kubectl get replicaset nginx-replicaset -o wide
```

Get detailed ReplicaSet information

```
kubectl describe replicaset/nginx-replicaset
```

Check the current Pods running

```
kubectl get pods
```

Delete a Pod of the ReplicaSet

```
FIRST_POD=$(kubectl get pods -l app=nginx -o jsonpath='{.items[0].metadata.name}')
```

```
kubectl delete pod $FIRST_POD
```

Recheck running Pods

```
kubectl get pods
```

Change image in yaml to nginxdemos/hello:v0.2 and apply replicaset again

```
kubectl apply -f nginx-replicaset.yaml
```

You will encounter that the replicaset was updated - but the pods are still using the old image

```
kubectl describe replicaset/nginx-replicaset
```

```
kubectl describe pod/<podname>
```

You have to kill and recreate the pods, so the new ones will be created with the new image. (see Hint section)

```
FIRST_POD=$(kubectl get pods -l app=nginx -o jsonpath='{.items[0].metadata.name}')
```

```
kubectl scale rs nginx-replicaset --replicas=0
```

```
kubectl scale rs nginx-replicaset --replicas=3
```

```
kubectl describe pod/$FIRST_POD
```

Create a Deployment (imperative method)

nginx-deployment.yaml

```
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: nginx-deployment
  name: nginx-deployment
spec:
  replicas: 25
```

```
selector:
  matchLabels:
    app: nginx-deployment
strategy:
  rollingUpdate:
    maxSurge: 25%
    maxUnavailable: 25%
  type: RollingUpdate
template:
  metadata:
    creationTimestamp: null
  labels:
    app: nginx-deployment
spec:
  containers:
    - image: nginxdemos/hello:0.4
      imagePullPolicy: Always
      name: hello
      ports:
        - containerPort: 80
          protocol: TCP
      resources: {}
status: {}
```

Create nginx deployment with the default of one replica

```
kubectl create deployment nginx-deployment --image=nginxdemos/hello --port=80
```

Create nginx deployment with three replicas

```
kubectl create deployment nginx-deployment --image=nginxdemos/hello --port=80 --replicas=3
```

Check deployment

```
kubectl get deployment -o wide
```

Get detailed deployment information

```
kubectl describe deployment
```

Get ReplicaSet information created by deployment

```
kubectl get replicaset -o wide
```

Get History for deployment

```
kubectl rollout history deployment/nginx-deployment
```

Annotate initial history entry

```
kubectl annotate deployment/nginx-deployment kubernetes.io/change-cause="init nginx deployment"
```

```
kubectl rollout history deployment/nginx-deployment
```

Scale up/down deployment (scale is not changing history)

```
kubectl scale deployment/nginx-deployment --replicas=2; watch kubectl get pods -o wide
```

```
kubectl scale deployment/nginx-deployment --replicas=20; watch kubectl get pods -o wide
```

Run update and rollback

```
FIRST_POD=$(kubectl get pods -l app=nginx-deployment -o jsonpath='{.items[0].metadata.name}')
```

Check image name

```
kubectl get pod $FIRST_POD -o jsonpath='{.spec.containers[0]}'
```

```
kubectl get deployment/nginx-deployment -o yaml > nginx-deployment.yaml
```

check Update yaml modifications under code section

```
kubectl apply -f nginx-deployment.yaml && kubectl rollout status deployment/nginx-deployment
```

```
kubectl annotate deployment/nginx-deployment kubernetes.io/change-cause="update new version"
```

```
kubectl rollout history deployment/nginx-deployment
```

Recheck image name after update

```
kubectl get pod $FIRST_POD -o jsonpath='{.spec.containers[0]}'
```

Check replicaset

```
kubectl get replicaset
```

Rollback to previous revision

```
kubectl rollout undo deployment/nginx-deployment --to-revision=1 && kubectl rollout status deployment/nginx-deployment
```

```
kubectl rollout history deployment/nginx-deployment
```

check pod image, as it was reverted to old revision

```
FIRST_POD=$(kubectl get pods -l app=nginx-deployment -o jsonpath='{.items[0].metadata.name}')
```

```
kubectl get pod $FIRST_POD -o jsonpath='{.spec.containers[0]}'
```

Run into failed state (change image in yaml to nginxdemos/hello:5.1)

```
kubectl apply -f nginx-deployment.yaml && kubectl rollout status deployment/nginx-deployment
```

```
kubectl annotate deployment/nginx-deployment kubernetes.io/change-cause="failed version"
```

```
kubectl rollout history deployment/nginx-deployment
```

```
kubectl rollout undo deployment/nginx-deployment --to-revision=3 && kubectl rollout status deployment/nginx-deployment
```

```
# check pod image, as it was reverted to healthy revision
FIRST_POD=$(kubectl get pods -l app=nginx-deployment -o jsonpath='{.items[0].metadata.name}')
kubectl get pod $FIRST_POD -o jsonpath='{.spec.containers[0]}'
kubectl rollout history deployment/nginx-deployment

# Pause from deployment
kubectl rollout pause deployment nginx-deployment
kubectl set image deployment/nginx-deployment nginx=nginx:1.22
kubectl get deployment nginx-deployment -o yaml | grep paused
kubectl rollout resume deployment nginx-deployment
kubectl rollout status deployment nginx-deployment

# Delete deployment
kubectl delete deployment/nginx-deployment
```

Hints

Deployments manage **ReplicaSets**, primarily due to historical reasons. There is no practical need to manually create ReplicaSets (or previously, ReplicationControllers), as Deployments, built on top of ReplicaSets, offer a more user-friendly and feature-rich abstraction for managing the application lifecycle, including replication, updates, and rollbacks.

ReplicaSets do not support auto updates. As long as required number of pods exist matching the selector labels, replicaset's job is done.

When a **rollback** is applied to a Deployment, Kubernetes creates a new history revision for the rollback. It doesn't simply go back to an old revision but treats the rollback as a new change. This means the rollback gets its own revision number, while the previous revisions remain saved. This helps you keep track of all changes, including rollbacks.
